Assignment 6

- Due **Friday 12/2, 11:59pm KST**
- Convolutional networks
  - Modularized implementation (loss is given!)
  - BatchNorm is given, but should be plugged into DeepConvNet

- Before submitting your work, we recommend you
  - Re-download clean files
  - Copy-paste your solution to clean py
  - Re-run clean ipynb only once
- If you feel difficult, consider to take **option 2**.

Assignment 7

- Due **Wednesday 12/14, 11:59pm KST**
- PyTorch autograd and nn
  - 3 different abstraction levels
  - Residual networks

- Before submitting your work, we recommend you
  - Re-download clean files
  - Copy-paste your solution to clean py
  - Re-run clean ipynb only once
- If you feel difficult, consider to take **option 2**.

Convolution as Matrix Multiplication (1D Example)

We can express convolution in terms of a matrix multiplication

$$\boldsymbol{x} * \boldsymbol{a} = \boldsymbol{X}\boldsymbol{a}$$

$$\begin{bmatrix} x & y & z & 0 & 0 & 0 \\ 0 & x & y & z & 0 & 0 \\ 0 & 0 & x & y & z & 0 \\ 0 & 0 & 0 & x & y & z \end{bmatrix} \begin{bmatrix} 0 \\ a \\ b \\ c \\ d \\ 0 \end{bmatrix} = \begin{bmatrix} ay + bz \\ ax + by + cz \\ bx + cy + dz \\ cx + dy \end{bmatrix}$$

Example: 1D conv, kernel size=3, stride=1, padding=1

Transposed convolution multiplies by the transpose of the same matrix:

$$\boldsymbol{x} *^T \boldsymbol{a} = \boldsymbol{X}^T \boldsymbol{a}$$

$$\begin{bmatrix} x & 0 & 0 & 0 \\ y & x & 0 & 0 \\ z & y & x & 0 \\ 0 & z & y & x \\ 0 & 0 & z & y \\ 0 & 0 & 0 & z \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ d \end{bmatrix} = \begin{bmatrix} ax \\ ay + bx \\ az + by + cx \\ bz + cy + dx \\ cz + dy \\ dz \end{bmatrix}$$

When stride=1, transposed conv is just a regular conv (with different padding rules)

Convolution as Matrix Multiplication (1D Example)

We can express convolution in terms of a matrix multiplication

$$\boldsymbol{x} * \boldsymbol{a} = \boldsymbol{X}\boldsymbol{a}$$

$$\begin{bmatrix} x & y & z & 0 & 0 & 0 \\ 0 & 0 & x & y & z & 0 \end{bmatrix} \begin{bmatrix} 0 \\ a \\ b \\ c \\ d \\ 0 \end{bmatrix} = \begin{bmatrix} ay + bz \\ bx + cy + dz \end{bmatrix}$$

Example: 1D conv, kernel size=3, stride=2, padding=1

Transposed convolution multiplies by the transpose of the same matrix:

$$\boldsymbol{x} *^T \boldsymbol{a} = \boldsymbol{X}^T \boldsymbol{a}$$

$$\begin{bmatrix} x & 0 \\ y & 0 \\ z & x \\ 0 & y \\ 0 & z \\ 0 & 0 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} ax \\ ay \\ az + bx \\ by \\ bz \\ 0 \end{bmatrix}$$

When stride>1, transposed convolution cannot be expressed as normal conv

Recall: PyTorch Convolution Layer

CLASS torch.nn.Conv2d(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *padding=0*, *dilation=1*, *groups=1*, *bias=True*, *padding_mode='zeros'*, *device=None*, *dtype=None*) [SOURCE]

Applies a 2D convolution over an input signal composed of several input planes.

In the simplest case, the output value of the layer with input size (N, C_{in}, H, W) and output $(N, C_{\text{out}}, H_{\text{out}}, W_{\text{out}})$ can be precisely described as:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{\text{in}}-1} \text{weight}(C_{\text{out}_j}, k) \star \text{input}(N_i, k)$$

where $\star$ is the valid 2D cross-correlation operator, N is a batch size, C denotes a number of channels, H is a height of input planes in pixels, and W is width in pixels.

Multiple Objects

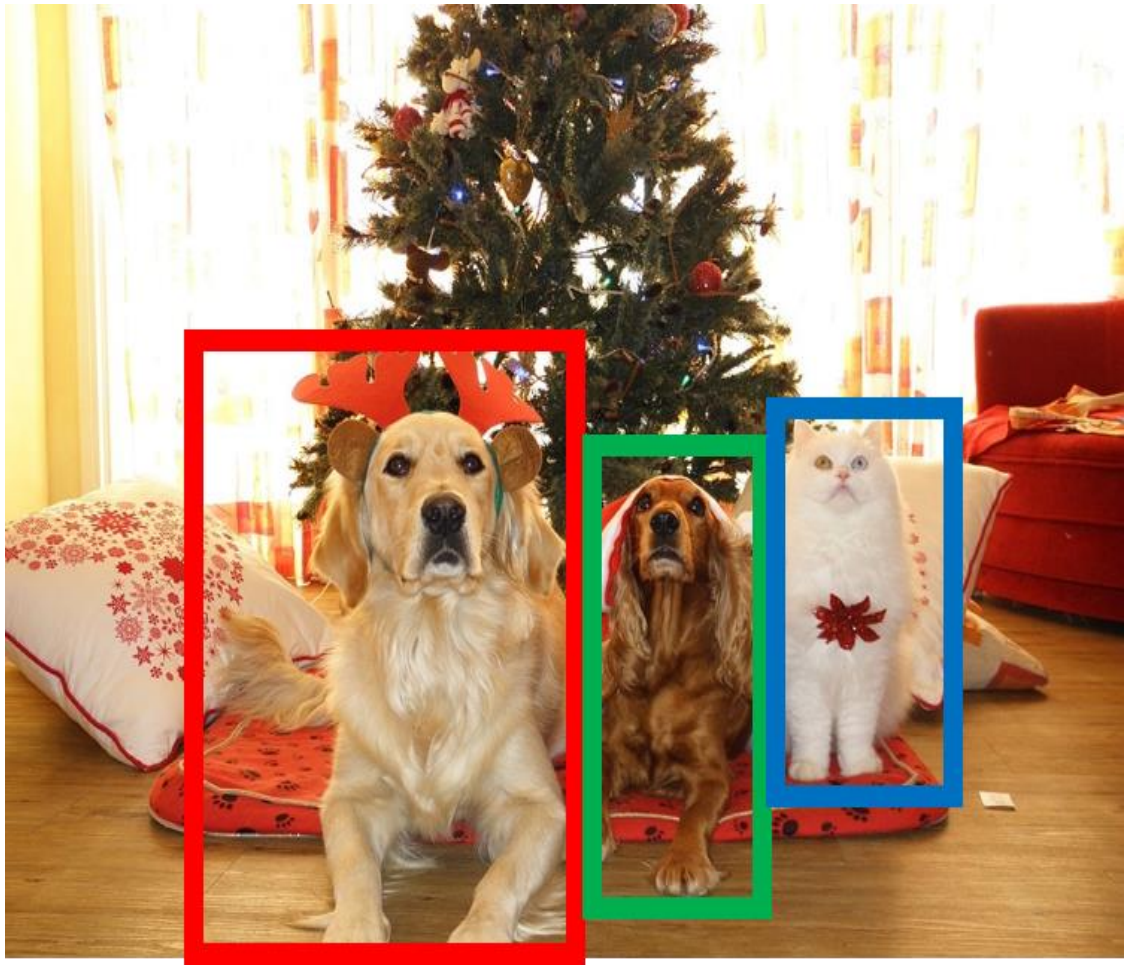
Object Detection: Task Definition

Input: Single RGB Image

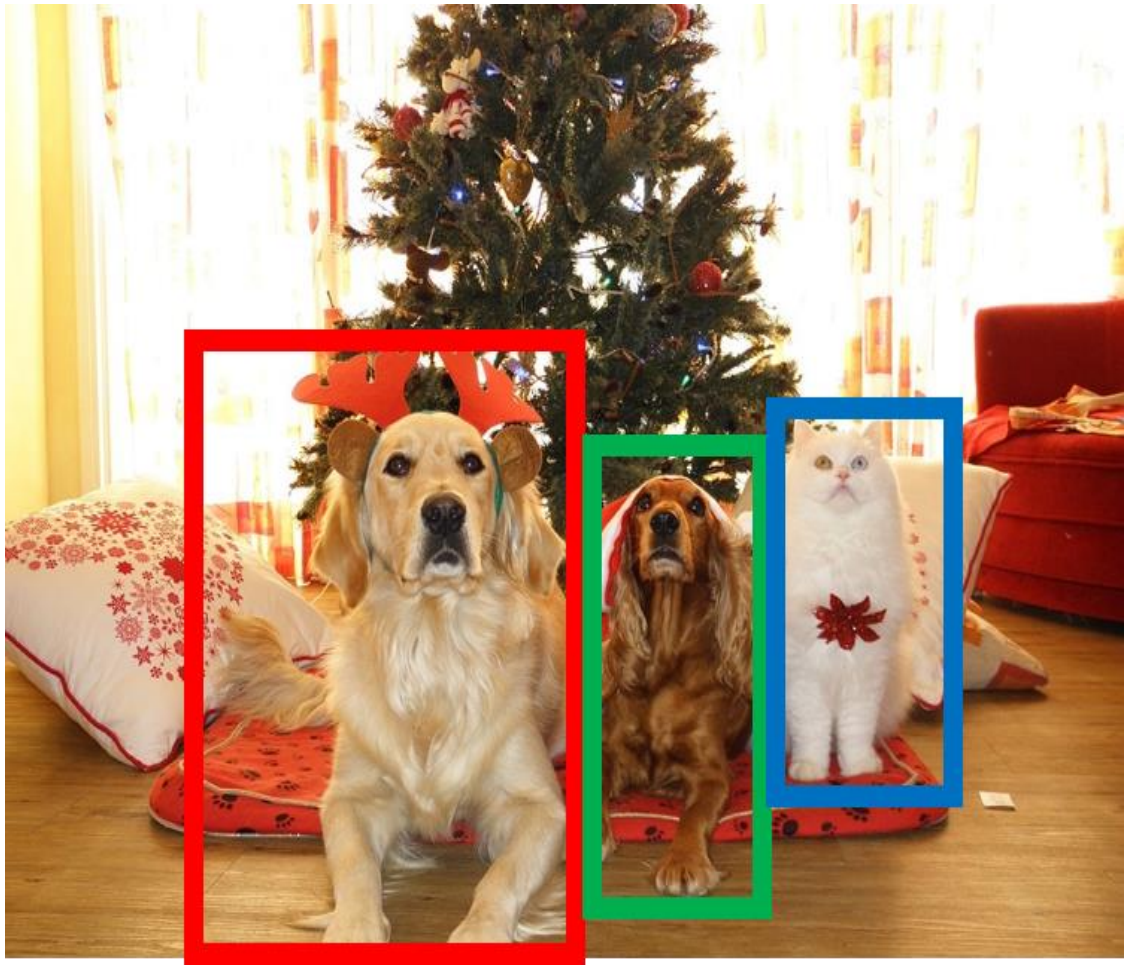
Output: A set of detected objects;
For each object, predict:

1. Category label (from fixed, known set of categories)
2. Bounding box (four numbers: x, y, width, height)



Object Detection: Challenges

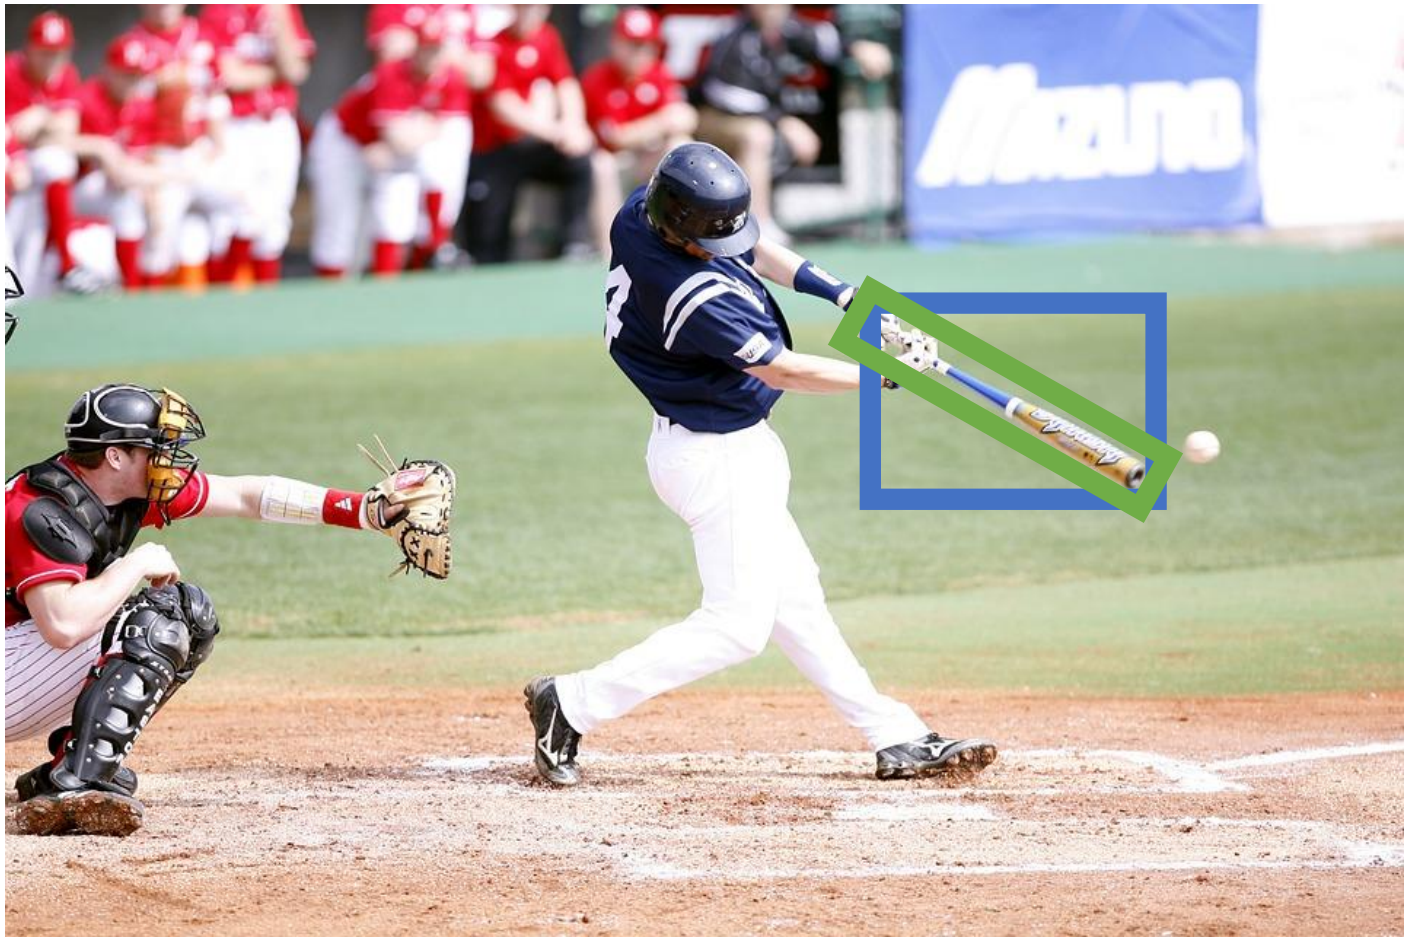
- **Multiple outputs**: Need to output variable numbers of objects per image
- **Multiple types of output**: Need to predict “what” (category label) as well as “where” (bounding box)
- **Large images**: Classification works at 224x224; need higher resolution for detection, often ~800x600



Bounding Boxes

Bounding boxes are typically *axis-aligned*

Oriented boxes are much less common



Comparing Boxes: Intersection over Union (IoU)

How can we compare our prediction to the ground-truth box?

Intersection over Union (IoU)
(Also called “Jaccard similarity” or “Jaccard index”):

Evaluating Detectors

- True detection: high IoU
- Precision: # true detections / # all detections
- Recall: # true detections / # ground truths

800 x 600 image has ~58M boxes! No way we can evaluate them all

Question: How many possible boxes are there in an image of size H x W?

Consider a box of size h x w:
Possible x positions: W – w + 1
Possible y positions: H – h + 1
Possible positions:
(W – w + 1) * (H – h + 1)

Total possible boxes:

$$\sum_{h=1}^{H}\sum_{w=1}^{W}(W-w+1)(H-h+1)$$

$$=\frac{H(H+1)}{2}\frac{W(W+1)}{2}$$

Region Proposals

- Find a small set of boxes that are likely to cover all objects
- Often based on heuristics: e.g., look for “blob-like” image regions
- Relatively fast to run; e.g., Selective Search gives 2000 region proposals in a few seconds on CPU

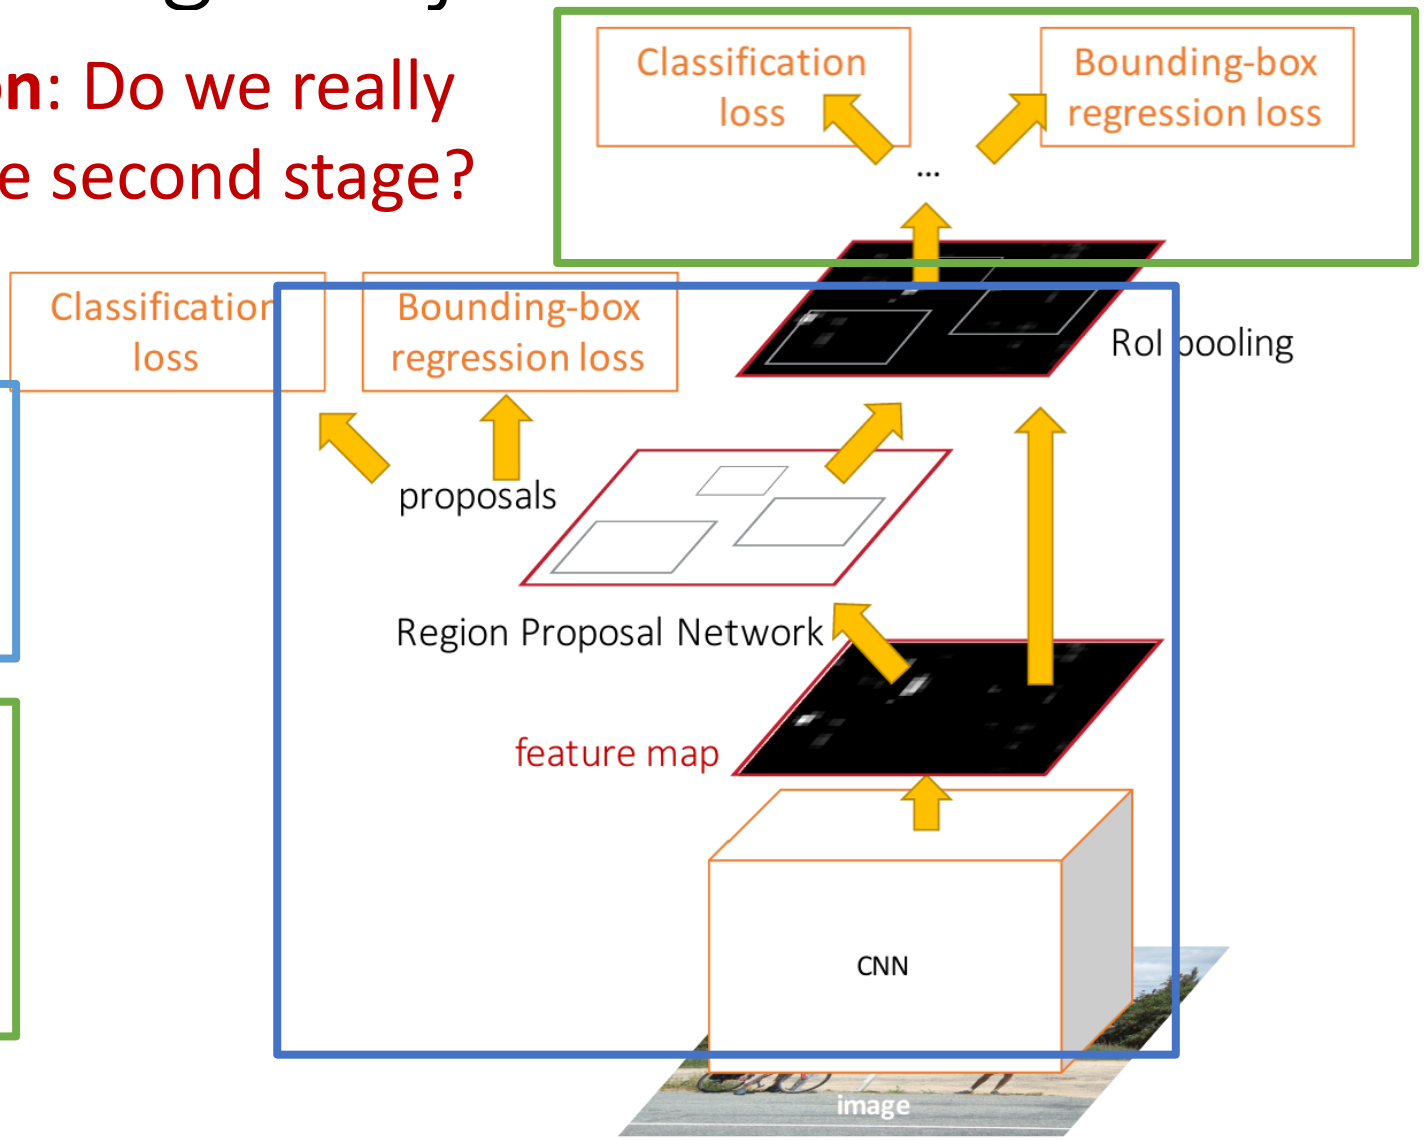
Faster R-CNN: Two-Stage Object Detector

Question: Do we really need the second stage?

Faster R-CNN is a
Two-stage object detector

First stage: Run once per image
- Backbone network
- Region proposal network

Second stage: Run once per region
- Crop features: RoI pool / align
- Predict object class
- Prediction bbox offset



Single-Stage Detectors: RetinaNet

Similar to RPN – but rather than classify anchors as object/no object, directly predict object category (among C categories) or background

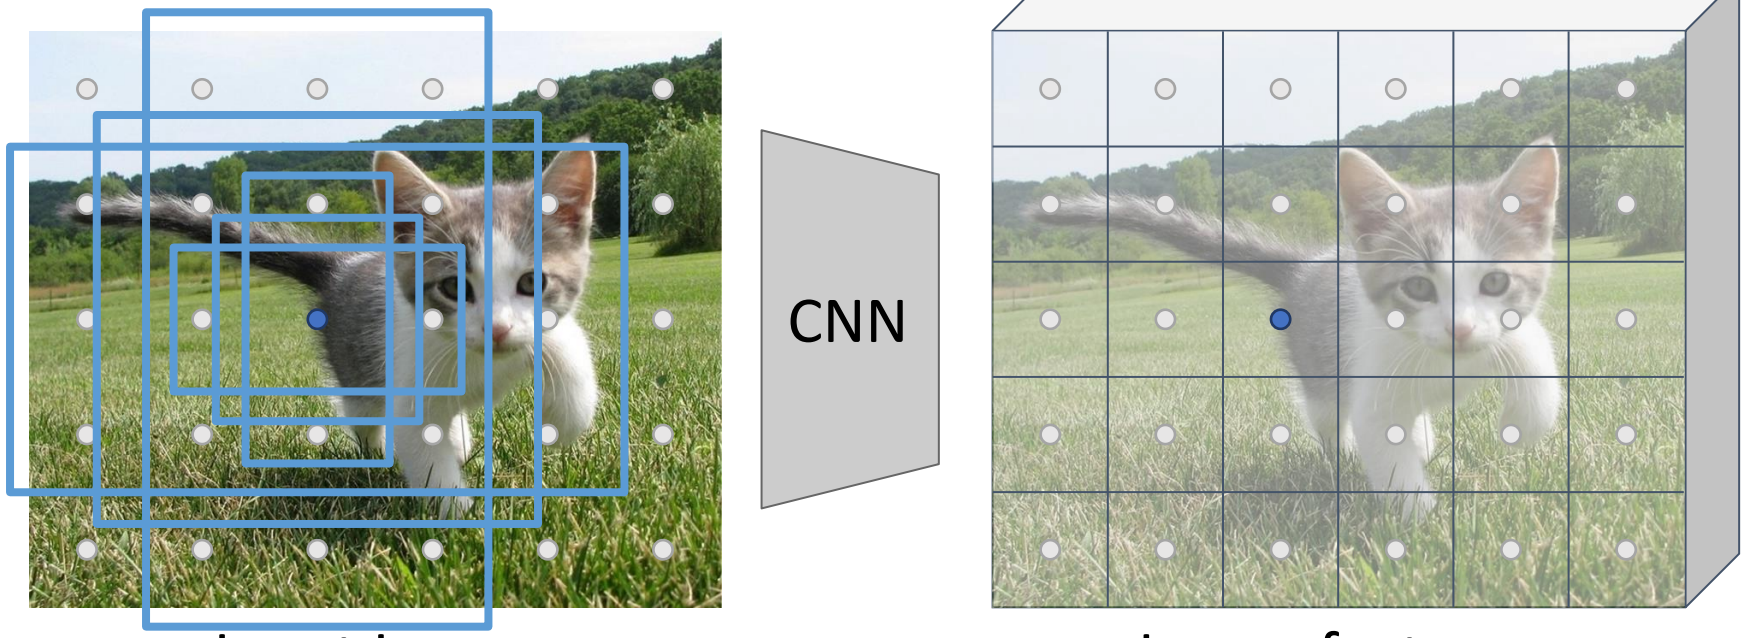
Each feature corresponds to a point in the input



Input Image

Single-Stage Detectors: RetinaNet

Problem: class imbalance – many more background anchors vs. non-background

Solution: "Focal Loss"; see the paper for details
